**INTERNATIONAL PRELIMINARY REPORT  
ON PATENTABILITY**

International application No.  
PCT/BR2005/000006

---

**Box No. I Basis of the report**

---

1. With regard to the **language**, this report is based on the international application in the language in which it was filed, unless otherwise indicated under this item.
- ☐ This report is based on translations from the original language into the following language , which is the language of a translation furnished for the purposes of:
- ☐ international search (under Rules 12.3 and 23.1(b))
  - ☐ publication of the international application (under Rule 12.4)
  - ☐ international preliminary examination (under Rules 55.2 and/or 55.3)
2. With regard to the **elements\*** of the international application, this report is based on *(replacement sheets which have been furnished to the receiving Office in response to an invitation under Article 14 are referred to in this report as "originally filed" and are not annexed to this report)*:

**Description, Pages**

1-7	as originally filed
8-22	received on 07.12.2005 with letter of 22.11.2005

**Claims, Numbers**

1-19	received on 07.12.2005 with letter of 22.11.2005
------	--

**Drawings, Sheets**

1/8-8/8	as originally filed
---------	---------------------

- ☐ a sequence listing and/or any related table(s) - see Supplemental Box Relating to Sequence Listing

3. ☐ The amendments have resulted in the cancellation of:

- ☐ the description, pages
- ☐ the claims, Nos.
- ☐ the drawings, sheets/figs
- ☐ the sequence listing (*specify*):
- ☐ any table(s) related to sequence listing (*specify*):

4. ☐ This report has been established as if (some of) the amendments annexed to this report and listed below had not been made, since they have been considered to go beyond the disclosure as filed, as indicated in the Supplemental Box (Rule 70.2(c)).

- ☐ the description, pages
- ☐ the claims, Nos.
- ☐ the drawings, sheets/figs
- ☐ the sequence listing (*specify*):
- ☐ any table(s) related to sequence listing (*specify*):

\* If item 4 applies, some or all of these sheets may be marked "superseded."

- 1). Following documents are referred to:  
D1: US2004005222  
D2: JP2003309994
- 2). D1, which is considered as the closest prior art, discloses a:
  - linear motor (1) in fig. 1 and 13 comprising a stator and an actuator, the stator being fed by a controlled voltage (V), the controlled voltage being applied to the linear motor and adjusted by a processing unit (20),
  - the linear motor (1) moving a load from the actuator displacement, the linear motor forming a resonant assembly with the load, the resonant assembly having a resonance frequency (fig. 8-10, par. 86),
  - the processing unit (20) being configured to control a displacement range (x) (in fig. 11, par. 69) of the actuator by means of the controlled voltage(V).
- 3). Differences between D1 and claim 1:
  - the processing unit (22) is selectively increasing or decreasing the displacement range in a proportional manner to the variations of the resonance frequency throughout the load variations and to dynamically **keep** the resonant assembly in resonance.
- 4). D1 proposes controlling the linear motor drive on constant displacement amplitude of the piston, which is a usual case: The piston has to move between two given points, irrespective how the losses are for that. The displacement is kept constant. Thus, the skilled person, trying to carry out compressor drive control independent of the load, has no reason to control the oscillating arrangement consisting of the spring supported linear motor and the load, which is the compressor fluid, on constant resonance frequency. Then it sufficient to only cover the losses from the oscillation friction of the spring through the linear motor, the rest is carried out by the spring resonance frequency. Claim 1 is therefore new and inventive (Art. 33(2) and (3) PCT).
- 5). The corresponding method claim 11 defines the steps for controlling the motor supply voltage, thus it is also new and inventive (Art. 33(2) and (3) PCT).
- 6). Claims 2-10 and 12-19 define details of the linear compressor drive with resonance frequency control and are therefore also new and inventive (Art. 33(2) and (3) PCT).

- 7). When entering the European Phase, two problems should be considered by the Applicant:
- a) The characterising part should apply to the fourth paragraph of claim 1, which differs from the prior art: "the processing unit ... in resonance".
  - b) Why there are still more than one device and method claims, despite the remarks in the foregoing communication.

creases (demanded by the cooling system at the suction valve of the linear compressor), this means that a thermal load has been put into the cooler. This warmer mass raises the temperature of the internal environment of the cooling system, causing the rise in the evaporation pressure, since the cooling liquid is in a saturated liquid state, and one can conclude that the pressure and the temperature are intrinsically interconnected. Thus, the fact of placing something warmer in the cooler, will result in a rise in pressure, raising the pressure of the gas on the piston, causing the resonance of the mechanism to decrease, which will cause a phase shift in the linear compressor.

In practice, this means that, as the heat inside the cooler rises, the load of the system also rises, causing the resonance frequency of the system to rise, and the piston stroke should be increased, which results in reducing of resonance frequency, since the piston stroke is longer. In this case, that difference by which the resonance frequency has risen as a function of the load added to the system, may cause the system to operate again at the previous frequency (or resonance frequency), increasing the piston displacement, leading the assembly to operate in resonance frequency.

On the other hand, a decrease in the load of the system (frozen food, lowering the ambient temperature) leads to an increase in the system phase, which may render the phase positive and compensate with a decrease in the system capacity until the phase reaches the zero value.

In this way, while the phase shift is positive, one should decrease the cooler capacity, to have the system operating again in resonance and, when the phase shift is negative, the capacity of the linear compressor should be increased, to have the system operating again in resonance.

One of the objectives of the present invention is achieved by means of a linear motor comprising a stator and an actuator, the stator being fed by a controlled voltage, the controlled voltage being applied to the linear motor and adjusted by a processing unit by means of a variable frequency inverter, the linear motor having a voltage frequency, the linear motor moving a load from the actuator displacement, the linear motor forming a resonant

assembly with the load, the resonant assembly having a resonance frequency, the processing unit is configured to control a displacement range of the actuator by means of the controlled voltage, the processing unit selectively increasing or decreasing the displacement range in a proportional manner to the variations of the resonance frequency throughout the load variations and to dynamically keep the resonant assembly in resonance.

Further, one of the objectives of the present invention is achieved by means of a linear compressor applicable to a cooling system, the linear compressor comprising a piston driven by a linear motor, the piston having a displacement range controlled by a controlled electric voltage, the controlled electric voltage having a voltage frequency applied to the linear motor and adjusted by a processing unit, the processing unit being configured to dynamically control the range of piston displacement as a function of the variable demand of the cooling system, the linear compressor having a resonance frequency, the processing unit adjusting the range of piston displacement so that the linear compressor will be dynamically kept in resonance throughout the variations in demand of the cooling system, the control of the pistons displacement being made by means of the controlled voltage that is adjusted by means of a variable frequency inverter, the inverter dynamically adjusting the voltage frequency of the controlled voltage to a value equal to the value of the resonance frequency of the linear compressor, as the variations in demand of the cooling system occur.

The objectives of the present invention are also achieved by means of a method of controlling a linear compressor, the linear compressor comprising a piston driven by a linear motor, the linear motor being fed by a controlled voltage having a voltage frequency of the linear motor and generating a capacity of the linear compressor, the method comprises the following steps of: measuring the feed frequency of the linear motor and compensating the feed frequency by comparing the measurement with a reference frequency and increasing the capacity if the linear compressor if the voltage frequency is higher than the reference frequency, or decreasing the capacity if the linear compressor if the voltage frequency is lower than the reference

frequency.

Further, the objectives of the present invention are achieved by means of a method of controlling a linear compressor, which comprises steps of measuring a feed phase of the feed current and a dynamic phase of the piston of the linear compressor, and measuring and establishing a measured phase, and dynamically adjusting the displacement range as a function of a variation in the demand of the linear compressor, so that the linear compressor will be kept in resonance throughout the variations in the demand of the cooling system so that the value of the measured phase will be null.

The teachings of the present invention are further carried out by means of a cooling system comprising a linear compressor, the cooling system comprising an on/off thermostat actuating the linear compressor, a linear compressor comprising a piston driven by a linear motor a piston having a displacement range controlled by means of a controlled voltage, the controlled voltage having a voltage frequency applied to the linear motor and adjusted by a processing unit, the range of piston displacement being dynamically controlled in junction of a variable demand of the cooling system during the period when the thermostat turns on the linear compressor, the linear compressor having a resonance frequency, the processing unit adjusting the range of piston displacement so that the linear compressor will be dynamically kept in resonance throughout the variations in demand of the cooling system, the displacement being adjusted through the controlled voltage by means of a variable frequency inverter, the inverter dynamically adjusting the voltage frequency of the controlled voltage to a value equal to the resonance frequency of the linear compressor, as the variations in demand of the cooling system occur.

#### Brief Description of the Drawings

The present invention will now be described in greater detail with reference to embodiments represented in the drawings. The figures show:

- Figure 1 is a schematic view of a linear compressor;
- Figure 2 is a diagram of the control system, of the linear compressor and of the cooling system of the present invention;

- Figure 3 is a block diagram of the control system, the linear compressor and the cooling system, illustrating the use with a conventional thermostat;

5     - Figure 4 is a block diagram of the control system of the present invention;

- Figure 5 is a block diagram of the algorithm of automatic control of the capacity applicable to the linear compressor and the cooling system of the present invention;

10    - Figure 6 represents a curve of the load of the electric motor in function of the phase;

- Figure 7 represents a curve of the capacity of the electric motor in function of the phase for various loads;

15    - Figure 8 is a time diagram illustrating the wave forms of the voltage network, counter-electromotive force (CEMF), current of the electric motor, position of the piston and signal of the sensor in the situation in which the linear compressor is operating at the resonance ( $\phi_{PC} = \phi_P - \phi_C = 0$ );

20    - Figure 9 is a time diagram illustrating the wave forms of the voltage network, counter-electromotive force (CEMF), current of the electric motor, position of the piston and signal of the sensor in the situation in which the linear compressor is operating above the resonance ( $\phi_{PC} = \phi_P - \phi_C > 0$ );

25    - Figure 10 is a time diagram illustrating the wave forms of the network voltage, counter-electromotive force (CEMF), current of the electric motor, position of the piston and signal of the sensor in the situation in which the linear compressor is operating below the resonance ( $\phi_{PC} = \phi_P - \phi_C < 0$ );

- Figure 11 is a flow diagram of the method for controlling the linear compressor of the present invention;

- Figure 12 represents a curve of the load of the electric motor in function of the phase, when the teachings of the present invention are employed, according to a second preferred embodiment;

and

- Figure 14 represents a flow diagram of the method for controlling the linear compressor, according to a second embodiment of the present invention.

## 5 Detailed Description of the Figures

As can be seen, Figure 2 illustrates a system comprising a cooler/refrigerator with the embarked electronics. In this case, an electronic thermostat 25 is integrated into the cooling system 20 and supplies a reference signal for the processing unit 22. The processing unit 22, in turn, controls the linear compressor 100, receiving a signal from the sensor SS corresponding to the displacement of the piston 1.

### Electronic Controls

Figure 3 illustrates a cooling system 20 applied to a simple-class cooler. As can be seen, in this case, the cooling system 20 supplies only a signal that turn the processing unit 22 on and off. In this way, the cooling system 20 can dispense all the electronics foreseen in the coolers/cooling systems that comprise embarked electronics. Moreover, with this construction the processing unit 22 can be integrated to the linear compressor 100 (see indication 31), which may be supplied for various coolers/refrigerator/cooling systems 20 manufacturers, resulting in an equipment with high flexibility when compared with pieces of equipment of the prior art. A proximity sensor 30 associated to the processing unit 22 will provide the position of the piston 1 when the latter comes close to the respective stroke end. In practice, minor variations in the piston stroke correspond to great variations in the capacity of the linear compressor, so that, by way of example, for a maximum stroke of 8.5 mm (maximum capacity) the minimum stroke would be about 6.5 mm (capacity close to zero), that is, about 2 mm of stroke variation range for the capacity to vary from zero to the maximum.

Figure 4 illustrates a detail of the processing unit 22. As can be seen, the processing unit 22 comprises a microcontroller 40, which controls a TRIAC 41 through a gate 42. The microcontroller 40 receives the signals of detection of zero of the network  $V_{AC}$  voltage ZT, as well as the zero signal of

the current ZC at the exit of the TRIAC 41. A displacement reference signal REF may be supplied by the cooler, if a cooler with embarked electronics is used. The main signal for the present invention refers to the displacement signal DP, which is obtained from the signal SS of the proximity sensor 30 and that should be treated, for instance, according to the teachings of Brazilian patent document PI 0301969-1, the description of which is incorporated herein by reference. Optionally, one may use the value of the feed current  $i_A$  at a moment different from ZC; for this purpose, one should make the necessary adjustments in order to have the correct measurements.

#### 10 Control Algorithm

Figure 5 illustrates the algorithm according to a first embodiment of the present invention for obtaining the controlled voltage  $V_M$  that should be applied to the linear motor 10, so that one can keep the linear compressor 100 in resonance. As can be seen, in order to calculate the value of the controlled voltage  $V_M$ , it is necessary to calculate a measured phase  $\phi_{PC}$ , which is obtained from the difference between the dynamic phase  $\phi_P$  and the current feed phase  $\phi_C$ :

$$\phi_{PC} = \phi_P - \phi_C$$

20

The calculation of the current phase or feed phase  $\phi_C$  is made from the zero of the current ZC and from the zero voltage zero ZT, whereas the calculation of the piston-displacement phase or dynamic phase  $\phi_P$  is made from the piston-displacement signal DP and from the zero of the voltage ZT.

25

Further with respect to the obtention of the feed phase  $\phi_C$ , the feed current  $i_A$  may not have a passage by zero, which would make it possible to capture a pre-defined moment for establishing the zero of the current ZC. This may be observed, for instance, in Figures 8, 9 and 10, where the feed current  $i_A$  remains at zero for a certain period. In this case, one should consider the pre-defined moment as the average point of permanence of the feed current  $i_A$  at zero.

30

From the values of the dynamic phase  $\phi_P$  and the feed phase  $\phi_C$ , one can obtain the value of the measured phase  $\phi_{PC}$  and obtain the reference value of the maximum piston displacement  $DP_{REF}$  (displacement that one expects to achieve a defined physical position). This value may be obtained  
 5 by means of the algorithm of Figure 11.

Once the reference value of maximum piston displacement  $DP_{REF}$  has been obtained, it is sufficient to subtract from it the maximum piston displacement  $DP_{MAX}$  by the equation:

$$10 \quad E_{DP} = DP_{REF} - DP_{MAX}$$

to obtain the error value  $E_{DP}$  between reference maximum piston displacement  $DP_{REF}$  and the maximum of piston displacement  $DP_{MAX}$ .

From this result it is possible to obtain the value of a control voltage  $V_P$ , since its value is a function of the error  $E_{DP}$ . This relationship may be  
 15 observed in the flow diagram in figure 11. Therein one may change increasing capacity with increasing  $DP_{REF}$ , and may change decreasing capacity with decreasing  $DP_{REF}$ . Alternatively, one may also use, for instance, a traditional method such as a PID algorithm to alter  $DP_{REF}$ ; in this case, the calculation would be made from the following equation:  
 20

$$DP_{REF} = K_P \times \phi_{PC} + K_D \times \left( \frac{\partial \phi_{PC}}{\partial T} \right) + K_i \times \int \phi_{PC} \times \partial T$$

25 wherein  $K_P$  is a proportional constant,  $K_D$  is a derived constant and  $K_i$  is an integral constant, as known from the classic nomenclature in control.

Further one may directly increase or decrease the value of the control voltage  $V_P$ , since this value is a function of  $\phi_{PC}$ . In this case, in the flow chart of Figure 11, one may change increasing capacity with increasing  $V_P$ ,  
 30 and may change decreasing capacity with decreasing  $V_P$ , so that in this option one may also use some traditional method such as PID algorithm to alter  $V_P$  from  $\phi_{PC}$  by using the following equation:

$$V_p = K_p \times \phi_{PC} + K_D \times \left( \frac{\partial \phi_{PC}}{\partial t} \right) + K_i \times \int \phi_{PC} \times \partial t$$

The constants are the same as described before.

5 From the value of the control voltage  $V_p$  it is possible to adjust the controlled voltage  $V_M$  by calculating the trigger angle of the TRIAC.

According to the graph of Figures 6 and 7, increases in the system load (increase in room temperature, increase in the thermal load in the system) lead to a decrease in the system phase. If this increase in the load is  
10 large (see dashed line with indication of "maximum load" in Figure 7) the phase will go on to negative values; this can be compensated by an increase in the capacity of the system (increase in the piston stroke 1), which will increase the phase, so that successive increments in the capacity lead the phase to the zero value, that is to say, the system will be operating in resonance.  
15 In an equivalent way, a decrease in the load (see dashed line with indication of "minimum load" in Figure 7) the phase will go to positive values, and this variation can be compensated by an increase in phase, so that successive increments lead the value of the phase to zero, that is to say, the system will be operating in resonance.

20 As far as the manner of making the increase and the decrease in phase is concerned, the reading of the feed phase  $\phi_C$  and the dynamic phase  $\phi_P$  every cycle or semi-cycle should be foreseen. So, whenever the measured phase  $\phi_{PC}$  is different from zero, the control system should actuate on the piston displacement, and the reading of the dynamic phase  $\phi_{PC}$  may be made  
25 according to the teachings of Brazilian patent document PI 0300010-9, which is incorporated herein by reference.

The amplitude of the decrements should take into consideration the reaction of the system in response to the increment/decrement caused by the control system. Thus, if the value of the increment/decrement is high, a  
30 longer stabilization time will be required; in the contrary case, the stabilization time will be shorter. Typically, the stabilization time depends upon the constants of the compressor time and of the cooling system. By way of example,

one may opt for awaiting a predetermined time, for instance about 10 to 60 seconds, or monitor the system phase until the latter remains constant.

Optionally, it is possible to use variable increment/decrement values. In this case, if the measured phase  $\phi_{PC}$  is large, one may use larger increments/decrements, and decrease this value as the value of the measured phase  $\phi_{PC}$  comes close to zero. In this case, one may opt for a reference value of 1% of increment/decrement.

Figure 8 shows a time diagram illustrating the wave forms of voltage of the network  $V_{AC}$  of the counter-electromotive force (CEMF), of the current  $i_A$  of the linear motor 10, of the piston position DP and of the signal of the proximity sensor (not shown) in the situation where the linear compressor 100 is operating in resonance, that is to say, when  $\phi_{PC} = \phi_P - \phi_C = 0$ .

As can be seen, in the situation of resonance, the piston displacement is maximum when the feed current  $i_A$  of the linear motor 10 passes by zero, a moment when the proximity sensor shows a measurable signal (see indication 80). In this condition, linear compressor 100 operates in optimum condition, since in this case the feed current  $i_A$  passes by zero at the moment when the piston 1 is changing direction in its path, that is to say, it passes by a moment of maximum displacement, when there is no need for application of force onto it, since when the piston 1 is at mid-displacement (see indication 82) the feed current  $i_A$  and the CEMF are maximum, impelling the piston 1 in the most effective way possible.

In Figure 9 one can observe that the linear compressor 100 is operating above the resonance, that is to say, the CEMF is in delay with respect to the feed current  $i_A$  of the linear motor 10. In this case, the equation is  $\phi_{PC} = \phi_P - \phi_C > 0$ , and one should increment the capacity of the linear compressor 100 by raising the controlled voltage  $V_M$ . It can be noted that, in this situation, when the piston 1 is at maximum displacement of its path, a moment when no feed current  $i_A$  should be applied to the linear motor 10, the feed current  $i_A$  already has a significant value at this moment. According to the same situation of phase shift, at the moment when the piston 1 is at the middle of its path (see indication 90), a moment when the maximum feed cur-

rent  $i_A$  should be applied to the linear motor 10, the feed current  $i_A$  has already undergone a decrease in its level, so that in the two situations there is a waste of energy and, therefore, a reduced efficiency in the operation of the linear compressor 100 as a whole.

5 In Figure 10 one can observe that the linear compressor is operating below the resonance; in this case the CEMF is advanced with respect to the feed current  $i_A$  of the linear motor 10, and the equation is then  $\phi_{PC} = \phi_P - \phi_C < 0$ . In this case, one should increment the capacity of the linear compressor 100, to have the system operating in resonance.

10 As can be seen, in this situation there is a delay in the phases, which causes the linear compressor to operate with low efficacy, since at the moment when the piston displacement is maximum, a situation on which no feed current  $i_A$  should be applied to the linear motor 10, one can observe that the feed current  $i_A$  is not null. Moreover, at the moment when the piston 1 is  
15 at the middle of the displacement (see indication 101), a moment when a maximum of feed current  $i_A$  should be applied to the linear motor 10, the feed current  $i_A$  is not maximum, so that, in this case too, the linear compressor 100 has its efficiency reduced.

#### Application in Linear Compressors

20 Structurally, the linear compressor 100 and the system of controlling a linear compressor 100 have the following characteristics:

The linear compressor 100 comprises a piston 1 and is driven by the linear motor 10, which brings about a displacement range that will be controlled through the controlled voltage  $V_M$ , this controlled voltage  $V_M$  having  
25 a voltage frequency  $f_P$ . The range of piston 1 displacement is dynamically controlled as a function of the variable demand of the cooling system 20, through the processing unit 22, which adjusts the range of piston displacement, so that the linear compressor 100 will be dynamically kept in resonance throughout the variations in demand of the cooling system 20, that is  
30 to say, so that its displacement range will be adjusted throughout the changes resulting from the variations in load demanded by the cooling system 20, impelling the linear compressor to operate in resonance. The system

of controlling the linear compressor 100, when taken in isolation, should be applicable to the linear compressor so as to make the dynamic adjustment of the displacement range, to have the linear compressor operating in resonance.

5 Application in Cooling Systems

The cooling system 20, which may include a cooler/refrigerator or an air-conditioning system and analogous systems, as already commented, should comprise an on/off thermostat actuated by the linear compressor 100, to have the range of piston displacement dynamically controlled as a function  
10 of the variable demand of the cooling system 20 during the period when the thermostat turns on the linear compressor. The processing unit 22 should dynamically adjust the range of piston displacement, so to keep the linear compressor in resonance throughout the variations of demand of the cooling system 20.

15 In order to control the linear compressor 100, the control system and the cooling system 20 of the present invention are provided with a method of controlling the linear compressor 100 that follows the flow chart illustrated in Figure 11.

The control over the range of piston 1 displacement is made by  
20 means of a controlled voltage  $V_M$ , which is adjusted by the processing unit 22. In order to adjust the level of the controlled voltage  $V_M$ , one may opt for following the teachings of a brazilian patent document PI 9907432-0, which is incorporated herein by reference.

Application in Linear motors

25 Bearing in mind that, with a control usable on linear compressors in general, one can make use of the teachings of the present invention on a linear motor 10 applied to other types of utilization. In this case, an actuator (not shown) has the same function of the piston 1 used in the compressor 100, that is to say, the actuator receives the force generated at the stator  
30 411, moving the load and forming a resonant assembly that will have a resonance frequency.

In an analogous way as foreseen for the control over the linear

compressor 100, the actuator has a displacement range that will be controlled by means of the controlled voltage  $V_M$  from the processing unit 22, so that the resonant assembly will be dynamically kept in resonance throughout the variations of load.

5           The control over the linear motor 10 may also be made by means of the processing unit 22, which measures the feed phase  $\phi_C$  of the feed current  $i_A$  and of the dynamic phase  $\phi_P$ , in this case of the actuator rather than of the piston, and adjusts the controlled voltage  $V_M$ , so that the value of the measured phase  $\phi_{PC}$  will be null.

10           Also, one may control the linear motor 10 by using a variable frequency inverter, which should be dynamically adjusted to the voltage frequency  $f_{VM}$  of the controlled voltage  $V_M$  to a value equal to the value of the resonance frequency of the resonant assembly, as the load variations occur.

#### Control Method by Phase Adjustment

15           In order to carry out the control method, the processing unit 22 monitors the range of piston 1 displacement throughout the operation of the linear compressor 100 and dynamically adjusts the displacement range as a function of a variation in demand of the linear compressor 100, so that the linear compressor 100 will be kept in resonance throughout the variations in  
20 demand of the cooling system 20.

          In order to impel the linear compressor 100 to operate in resonance, one measures the feed phase  $\phi_C$  of a feed current  $i_A$  and the dynamic phase  $\phi_P$  of the piston 1 of the linear compressor 100 and measures the difference between the measured phases to establish the measured phase  $\phi_{PC}$ .

25           After the step of establishing the measured phase  $\phi_{PC}$ , one should increment the range of piston 1 displacement when the value of the measured phase  $\phi_{PC}$  is positive or a step of decreasing the range of piston 1 displacement when the value of the measured phase  $\phi_{PC}$  is negative, and one should always increase or decrease the displacement of the piston 1 to a  
30 value necessary for the measured phase  $\phi_{PC}$  to be null.

          By preference, after the step of increasing or decreasing the range of piston 1 displacement, one should wait until a stabilization time has

passed before measuring again the difference between the feed phase  $\phi_c$  and the dynamic phase  $\phi_p$ .

#### Control Method by Adjustment of Phase Frequency

According to a second preferred embodiment of the present invention, another way of controlling the compressor to control the frequency applied to the motor to keep it will always operating in resonance.

In this case, the control is made through the variable frequency, by using a variable frequency inverter (not shown). In this way, when the load applied to the linear compressor 100 is changed, there will also be a change on the dynamic phase  $\phi_p$  of the system, which will be detected by the control system of the present invention, in order to alter the frequency for the compressor to operate in resonance. This control is dynamically made by adjusting the voltage frequency  $f_{VP}$ , through the variable frequency inverter, to a value equal to the resonance frequency of the linear compressor 100, as the variations in demand of the cooling system 20 occur.

The ways of making this kind of adjustment may include, for example, varying the frequency so as to minimize the feed current or else varying the frequency so as to zero the phase between current and the CEMF.

As can be seen in Figures 12 and 13, when the load increases, the frequency of the linear compressor 100 increases, and one should increment the respective capacity, to have the system operating in resonance and vice-versa, when the load decreases, that is to say, the system should increase the piston 1 stroke/capacity/compressor 100 and, when the frequency decreases, the control system should decrease the stroke/capacity. In the same way as in the first preferred embodiment of the present invention, it is possible to operate the cooling system by means of a simple "On/Off"-type thermostat, maintaining the same concept of adjustment of the piston 1 (capacity of the compressor 100) by varying the frequency.

In this regard, one can observe that the basic concept between the first preferred embodiment of the present invention and the second embodiment is similar, that is to say, one can observe the effect of the change in the load applied to the compressor with respect to the resonance frequency,

and, with this information, alter the piston stroke (compressor capacity).

With the control method in this embodiment, one can proceed in accordance with the flow diagram shown in Figure 14 and following these steps:

- 5                    measuring the feed frequency of the linear motor 10, which is the voltage frequency  $f_{VP}$ , and then making the compensation of this measurement with the value of a reference frequency FR, which is usually of 50 or 60 Hz.

- 10                   In this compensation step, if the voltage frequency  $f_{VP}$  is higher than the reference frequency FR, one should increment the capacity of the linear compressor 100. If the voltage frequency  $f_{VP}$  is lower than the reference frequency FR, one should decrease the capacity of the linear compressor 100.

- 15                   To have these methods of the first and second embodiment operating in the best possible condition for the system, the linear compressor 100 has to be designed to operate in resonance when the system is stabilized and at low capacity (in this condition, the system should operate 80% of the time). In this way, when a greater capacity is necessary, the algorithm will increase the capacity of the linear compressor 100.

- 20                   Another ability which the algorithm should have is the function of maximum (rapid) freezing. In a freezer, when this function is active, the linear compressor 100 will function for 24 hours without cycling; in systems with variable capacity, the linear compressor should function at the maximum capacity, regardless of the load or internal temperature. In order to perform this  
25                   function, the algorithm may measure the cycle time, if this time is longer than a reference (for instance, 2 hours); the algorithm will go to the maximum capacity independently of the phase condition and will only operate normally again when the system cycles or when the 24 hours have passed.

The advantages of the proposed solution are as follows:

- 30                   • it enables one to apply the linear compressor in simple systems, equipped with conventional thermostat and to use the advantages of the variable capacity;

- it reduces costs of the cooling/refrigerator system 20;
- it optimizes the functioning of the linear compressor (the linear compressor always works at the maximum efficiency);
- the performance of the linear compressor is improved;
- there is a correction in the pumping capacity of the linear compressor, adapted to the need of the cooling system 20.

Examples of preferred embodiments having been described, one should understand that the scope of the present invention embraces other possible variations, being limited only by the contents of the accompanying claims, which include the possible equivalents.

**CLAIMS**

1. A linear motor (10) comprising a stator (411) and an actuator, the stator (411) being fed by a controlled voltage ( $V_M$ ), the controlled voltage ( $V_M$ ) being applied to the linear motor (10) and adjusted by a processing unit  
5 (22) by means of a variable frequency inverter,

- the linear motor (10) moving a load from the actuator displacement, the linear motor (10) forming a resonant assembly with the load, the resonant assembly having a resonance frequency,

the linear motor (10) being characterized in that the processing  
10 unit (22) is configured to control a displacement range of the actuator by means of the controlled voltage ( $V_M$ ),

the processing unit (22) selectively increasing or decreasing the displacement range in a proportional manner to the variations of the resonance frequency throughout the load variations and to dynamically keep the  
15 resonant assembly in resonance.

2. A linear compressor (100) applicable to a cooling system (20), the linear compressor (100) comprising a piston (1) driven by a linear motor (10), the piston (10) having a displacement range controlled by a controlled electric voltage ( $V_M$ ), the controlled electric voltage ( $V_M$ ) having a voltage frequency ( $F_{VM}$ ) applied to the linear motor (10) and adjusted by a processing  
20 unit (22),

the linear compressor (100) being characterized in that the processing unit (22) is configured to dynamically control the range of piston (1) displacement as a function of the variable demand of the cooling system  
25 (20), the linear compressor (100) having a resonance frequency,

the processing unit (22) adjusting the range of piston displacement so that the linear compressor (100) will be dynamically kept in resonance throughout the variations in demand of the cooling system, the control of the pistons displacement being made by means of the controlled voltage  
30 ( $V_M$ ) that is adjusted by means of a variable frequency inverter, the inverter dynamically adjusting the voltage frequency ( $f_{VM}$ ) of the controlled voltage ( $V_M$ ) to a value equal to the value of the resonance frequency of the linear

compressor (100), as the variations in demand of the cooling system (20) occur.

3. A linear compressor according to claim 2, characterized in that the controlled voltage ( $V_M$ ) generates a feed current ( $i_A$ ) that circulates in the  
5 linear motor (10),

the processing unit (22) measuring a feed phase ( $\phi_C$ ) of the feed current ( $i_A$ ) and the dynamic phase ( $\phi_P$ ) of the piston (1) of the linear compressor (100),

the processing unit (22) measuring the difference between the  
10 feed phase ( $\phi_C$ ) and the dynamic phase ( $\phi_P$ ) and establishing a measured phase ( $\phi_{PC}$ ), the processing unit (22) adjusting the controlled voltage ( $V_M$ ) so that the value of the measured phase ( $\phi_{PC}$ ) will be null.

4. A linear compressor according to claim 3, characterized in that the controlled voltage ( $V_M$ ) is decreased when the value of measured phase  
15 ( $\phi_{PC}$ ) is positive and increased quant the measured phase ( $\phi_{PC}$ ) is negative.

5. A linear compressor according to claim 4, characterized in that the feed phase ( $\phi_C$ ) is obtained from a pre-defined moment of the feed current ( $i_A$ ).

6. A linear compressor according to claim 5, characterized in that  
20 the pre-defined moment of the feed current ( $i_A$ ) is the passage of the feed current ( $i_A$ ) by zero.

7. A linear compressor according to claim 6, characterized on that the pre-defined moment is obtained at the middle point of the permanence of the feed current ( $i_A$ ) at zero.

25 8. A linear compressor according to claim 7, characterized in that the dynamic phase ( $\phi_P$ ) is obtained from a signal of piston (1) displacement (DP).

9. A linear compressor according to claim 8, characterized in that the value of the dynamic phase ( $\phi_P$ ) is obtained by means of a displacement  
30 sensor (30) electrically associated to the processing unit (22).

10. A linear compressor according to claim 9, characterized in that the value of the dynamic phase ( $\phi_P$ ) is obtained from the position of pis-

ton (1) displacement (DP).

11. A method of controlling a linear compressor (100), the linear compressor (100) comprising a piston (1) driven by a linear motor (10), the linear motor (10) being fed by a controlled voltage ( $V_M$ ) having a voltage frequency ( $F_{VP}$ ) of the linear motor (10) and generating a capacity of the linear compressor (100),

the method being characterized in that it comprises the following steps of:

- measuring the feed frequency ( $f_{VP}$ ) of the linear motor (10) and compensating the feed frequency ( $f_{VP}$ ) by comparing the measurement with a reference frequency (FR) and increasing the capacity of the linear compressor (100) if the voltage frequency ( $f_{VP}$ ) is higher than the reference frequency (FR), or decreasing the capacity of the linear compressor (100) if the voltage frequency ( $f_{VP}$ ) is lower than the reference frequency (FR).

12. A method according to claim 11, characterized in that, after the step of increasing or decreasing the capacity of the linear compressor (100), there is a step of waiting the passage of a stabilization time.

13. A method according to claim 12, characterized in that, after the passage of the stabilization time, the feed frequency of the linear motor (100) is measured again.

14. A method of controlling a linear compressor (100), the linear compressor (100) comprising a piston (1) driven by a linear motor (10),

- the piston (1) having a controlled voltage ( $V_M$ ), the controlled voltage ( $V_M$ ) having a voltage frequency ( $f_{VM}$ ) applied to the linear motor (10) and adjusted by a processing unit (22),

controlled voltage ( $V_M$ ) generating a feed current ( $i_A$ ) that circulates in the linear motor (10),

the method being characterized by comprising the steps of:

- measuring a feed phase ( $\phi_C$ ) of the feed current ( $i_A$ ) and a dynamic phase ( $\phi_C$ ) of the piston (1) of the linear compressor (100), and
- measuring the difference between the feed phase ( $\phi_C$ ) and the

dynamic ( $\phi_P$ ) and establishing a measured phase ( $\phi_{PC}$ ),

- dynamically adjusting the range of displacement in function of a variation in demand of the linear compressor (100), so that the linear compressor will be kept in resonance throughout the variations in demand of the cooling system (20) so that the value of the measured phase ( $\phi_{PC}$ ) will be null.

15. A method according to claim 14, characterized in that, after the step of establishing the measured phase ( $\phi_{PC}$ ), there is a step of increasing the range of piston (1) displacement when the value of the measured phase ( $\phi_{PC}$ ) is positive or a step of decreasing the range of piston (1) displacement when the value of the measured phase ( $\phi_{PC}$ ) is negative.

16. A method according to claim 15, characterized in that, after the step of increasing or decreasing the range of piston (1) displacement, it is foreseen to await the passage of a stabilization time.

17. A method according to claim 16, characterized in that, after the passage of the stabilization time, there is a new measurement of the difference between the feed phase ( $\phi_C$ ) and the dynamic phase ( $\phi_P$ ).

18. A cooling system (20) comprising a linear compressor (100), the cooling system (20) comprising an on/off thermostat actuating the linear compressor (100),

a linear compressor (100) comprising a piston (1) driven by a linear motor (10)

a piston (1) having a displacement range controlled by means of a controlled voltage ( $V_M$ ), the controlled voltage ( $V_M$ ) having a voltage frequency ( $f_{MV}$ ) applied to the linear motor (10) and adjusted by a processing unit (22),

the cooling system (20) being characterized in that:

the range of piston (1) displacement is dynamically controlled in junction of a variable demand of the cooling system (20) during the period when the thermostat turns on the linear compressor (100),

the linear compressor (100) having a resonance frequency, the processing unit adjusting the range of piston (1) displacement so that the lin-

ear compressor (100) will be dynamically kept in resonance throughout the variations in demand of the cooling system (20),

the displacement being adjusted through the controlled voltage ( $V_M$ ) by means of a variable frequency inverter, the inverter dynamically adjusting the voltage frequency of the controlled voltage ( $V_M$ ) to a value equal to the resonance frequency of the linear compressor (100), as the variations in demand of the cooling system (20) occur.

19. A linear compressor (100) controlling system, the system being characterized by comprising a processing unit (20) measuring a range of piston (1) displacement and the processing unit adjusting the range of the piston (1) displacement to dynamically keep the linear compressor (100) in resonance throughout the variations in demand of the cooling system (20), the control central being configured to measure a feed phase ( $\phi_C$ ) of a feed current ( $i_A$ ) and a dynamic phase ( $\phi_P$ ) of the piston (1) of the linear compressor (100),

the processing unit (22) measuring the difference between the feed phase ( $\phi_C$ ) and the dynamic phase ( $\phi_P$ ) and establishing a measured phase ( $\phi_{PC}$ ), the processing unit (22) adjusting the controlled voltage ( $V_M$ ) so that the value of the measured phase ( $\phi_{PC}$ ) will be null.

the displacement being adjusted through the controlled voltage ( $V_M$ ) by means of a variable frequency inverter, the inverter dynamically adjusting the voltage frequency of the controlled voltage ( $V_M$ ) to a value equal to the resonance frequency of the linear compressor (100), as the variations in demand of the cooling system (20) occur.
